

Per-output-time error of the correction ladder. Blue = dense quadrature, red = empirical quadrature at the same q and the same M .
 The rungs separate only at $t = 0.05$, only in the empirical-quadrature arms, and the separation grows with q .

cheap-corrections `cclad01`, fixed $M = 256$
 worst over the six cases

the same arms, case 3 alone
 (the case that sets the worst)

b-ladder-top `btq201`, fixed $M = 256$
 worst over the six cases
